CS3570 Introduction to Multimedia Technology
Homework #2
Due: 11:59pm, 4/16/2019

Q1. Create your own FIR filters to filter audio signal (40%)
"**HW2_Mix.wav**" is a mix of 3 songs. Based on the **ideal impulse responses** given in slide #72 and the **windowing functions** in slide #75, you need to design and apply different FIR filters in time domain to separate the **three audio signals** from the given audio file. You can refer to the algorithm on slide #76. Next, you are asked to **reduce the sampling rates** of signals and compare them. Finally, the output audio signals are too simple so you should apply **one-fold echo** and **multiple-fold echo** (slide #69) to produce wonderful music.

1. Implement **3 different FIR filters** to separate the three audio signals with:
   - **Blackmann** window function (You have to pick the appropriate window size and cut-off frequency).
2. Implement **1-D convolution** on the input signal of the given audio with your filters.
3. Reduce the **sampling rates** of the three separated songs to 2000Hz.
4. Apply **one-fold echo** and **multiple-fold echo** on the audio signal that pass through the **low-pass filter**.(Please use the files before reducing sampling rates)
5. **Plot** the result.
   - The spectrum of the input signal
   - The spectrums of the output signals. **(before echo)**
   - The spectrums of the filters
   - The shapes of the filters (time domain)
6. Store the files.
   - **Store** the filtered audio files before reducing the sampling rates and name "**FilterName_[para1]_[para2].wav**".
   - **Store the** filtered audio files after reducing the sampling rates and name "**FilterName_[para1]_[para2]_2kHz.wav**".
   - **Store** the echo audio files and name **"Echo_one.wav"** and **"Echo_multiple.wav".**
7. In the report
   - Discuss how you determine the filters.
   - How you implement the filter and convolutions to separate the

mixed song and one/multiple fold echo.
- Compare spectrum and shape of the filters.
- Briefly compare the difference between signals before and after reducing the sampling rates.
- Anything worth mentioning

Q2. Audio dithering and noise shaping (60%)

There is an audio signal **"Tempest.wav"**. You are asked to apply **bit reduction** to reduce the signal from 16-bit to 8-bit. Due to the reduction, the audio will contain noise and sharp stair-step effect. To eliminate the noise, you need to apply **audio dithering**, **noise shaping** (slide #18), and use **low-pass filter** you finished in Q1 to filter out the high frequency components. Finally, since the volume is too small, you should apply **audio limiting** (slide #48) and **normalization** (slide #50) to get the louder audio signal. Follow the steps below and you can finish the homework easily.

1. **(Bit reduction)** Reduce the signal from 16-bit to 8-bit.
2. **(Audio dithering)** Add random noise (uniform distribution) into the signal
3. **(Noise shaping)** Apply the first-order feedback loop for noise shaping. Please choose the appropriate coefficient **c** yourself.
4. **(Low-pass filter)** Apply low-pass filter. Please choose the appropriate **cutoff frequency** yourself.
5. **(Audio limiting)** Apply hard clipping to the signal.
6. **(Normalization)** Apply normalization steps to the signal.
7. **Plot** the result
   - The shape and spectrum of input signals
   - The shape and spectrum of output signals
   - The shape and spectrum of the result of audio dithering and noise shaping
8. **Store** the audio file
   - The result of Bit reduction – **"Tempest_8bit.wav"**
   - The final output audio signal – **"Tempest_Recover.wav"**
9. In the report
   - How you implement the bit reduction, audio dithering, noise shaping, low-pass filter, audio limiting and normalization.
   - Discuss the effect of dithering and noise shaping according to the spectrums and shapes you plot

- Anything worth mentioning.

Reminder
- Follow the instructions (hints) and spec in the sample codes.
- You cannot use Matlab built-in function "conv" in this homework.
- Plot the spectrum and shape in appropriate range for better visualization.
- Please save the report as "[YourID]_report.pdf".
- Please provide a README file about how to execute your program.
- Please compress all the .m files, output audio files and report into a zip file and name it "HW2_[YourID].zip"
